The Most Important Diagram in Calculus

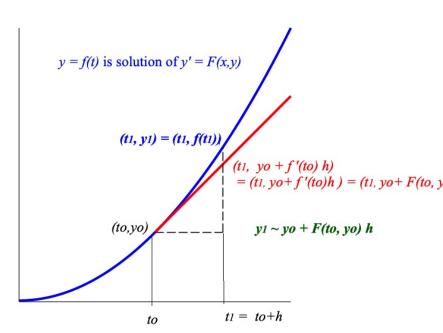

Linear Approximation

$$f(x) \approx f(a) + f'(a)h$$
 where $h = x - a$
Suppose f is the solution of the Differential Equation

 $y' = \frac{dy}{dx} = F(x, y)$ with initial condition $y_0 = f(x_0)$

Given
$$y' = F(x, y)$$
 with $f(t_0) = y_0$
 $y_1 = y_0 + F(t_0, y_0)$
 $y_2 = y_1 + F(t_1, y_1)h$ where $t_1 = t_0 + h$
 $y_3 = y_2 + F(t_2, y_2)h$ where $t_2 = t_1 + h$
 $y_4 = y_3 + F(t_3, y_3)h$ where $t_3 = t_2 + h$
...

 $y_{n+1} = y_n + F(t_n, y_n)h$ where $t_n = t_{n-1} + h$

Example: Consider the Differential Equation

$$y' = 3 + t - y$$
 with $y(0) = 1$

This is First Order Linear:

$$y' + y = 3 + t$$

Integrating Factor is $e^{\int 1dt} = e^t$

Example: Consider the Differential Equation

$$y' = 3 + t - y$$
 with $y(0) = 1$

This is First Order Linear:

$$y' + y = 3 + t$$

Integrating Factor is
$$e^{\int 1dt} = e^t$$

 $e^t y' + e^t y = 3e^t + te^t$

Example: Consider the Differential Equation

$$y' = 3 + t - y$$
 with $y(0) = 1$

This is First Order Linear:

$$y' + y = 3 + t$$

Integrating Factor is
$$e^{\int 1dt} = e^t$$

$$e^t \ y' + e^t \ y = 3e^t + te^t$$

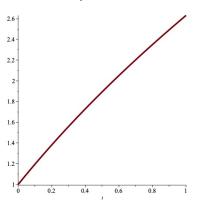

$$(e^t \ y)' = 3e^t + te^t$$

$$e^t \ y = 3e^t + te^t - e^t + C$$

$$y = 3 + t - 1 + Ce^{-t} = t + 2 + Ce^{-t}$$
Apply Initial Condition:
$$1 = 0 + 2 + C \text{ so } C = -1$$
Solution is $y = t + 2 - e^{-t}$

y' = 3 + t - y with y(0) = 1

Solution is $y = t + 2 - e^{-t}$

Euler's Method

$$y' = 3 + t - y$$
 with $y(0) = 1$
Solution is $y = t + 2 - e^{-t}$
Set Step Size $h = 0.1$

Set Step Size
$$h = 0.1$$

 $y_0 = 1$
 $y_1 = y_0 + y'(0)h = 1 + (3 + 0 - 1)h = 1 + 2h = 1 + 2(.1) = 1.2$

True Value is
$$.1 + 2 - e^{-.1} = 1.195162582$$

0.3

1.559181779

$$y_1 = y_1 + y'(.1)h = 1.2 + (3 + .1 - 1.2)(.1) = 1.2 + .19 = 1.39$$

	True V

Euler's Method with h = 0.1

$$y' = 3 + t - y$$
 with $y(0) = 1$
Solution is $y = t + 2 - e^{-t}$

What Can Go Wrong? Euler's Method with h = 0.1

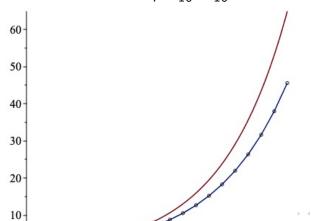

$$y' = 1 - t + 4y$$
 with $y(0) = 1$
Solution is $y = \frac{t}{4} - \frac{3}{16} + \frac{19}{16}e^{4t}$

What Can Go Wrong? Cut Step Size in Half Euler's Method with h = 0.05

$$y' = 1 - t + 4y$$
 with $y(0) = 1$
Solution is $y = \frac{t}{4} - \frac{3}{16} + \frac{19}{16}e^{4t}$

What Can Go Wrong? Euler's Method with h = 0.05 but extend the interval to [0,2]

$$y' = 1 - t + 4y$$
 with $y(0) = 1$
Solution is $y = \frac{t}{4} - \frac{3}{16} + \frac{19}{16}e^{4t}$
